

Determining When to Begin Corn and Soybean Planting

- Early planting may help maximize yield potential and reduce pest pressure for corn and soybean productions, but planting too early can be detrimental to the crop.
- Planting should be accomplished according to soil temperature and conditions as opposed to the calendar date.
- When soils warm up, a correct planting depth can help in establishing a good stand.

Ideal Planting Temperatures

Growers may anticipate an early planting season if spring temperatures are above average. Even when a warm spell occurs, it is important to consider the average temperature for the region over a span of several years. Finding the average air and soil temperatures from 10 or more years prior can help provide a better outlook on future weather conditions. For optimum germination, corn requires a soil temperature of at least 50° F¹ and soybean requires a soil temperature of 55 to 60° F.² If planting occurs before these optimal soil temperatures, seeds may remain dormant in the soil and become increasingly vulnerable to diseases, insects, and animal predators. Planting into cold and/or wet soils can lead to numerous problems.

Chilling Injury

Imbibitional chilling injury can occur to both corn and soybean seedlings. Seed imbibition is a two-step process; water is absorbed into the seed and the seed swells. Water intake activates enzymatic processes, such as increased respiration and cell duplication, which eventually result in germination and emergence. Imbibitional chilling injury can occur when the imbibed moisture comes from a cold source, such as chilling rain, causes the cell membrane to become rigid and can rupture. This may result in damaged or aborted radicles, lower germination, and delayed seedling growth. Such damage may limit or prevent nutrient uptake, restrict normal seedling development, and allow for soil disease and pest entry. Symptoms similar to chilling injury can also be caused by other factors and may be compounded by additional stresses during germination. These stresses may include herbicide injury, disease, or soil crusting. Since these symptoms are not unique to chilling injury, they can be hard to decipher. Typical symptoms of chilling injury may include a swollen seed that has not germinated and a fragile or absent primary root.

Corn Planting

Corn planting dates can range greatly depending on the region. Refer to the United States Department of Agriculture Field Crop Usual Planting and Harvest Dates (Handbook 628) for a range of planting dates for your state. This information can be located at <http://www.nass.usda.gov/> by searching for "Planting Date". In the United States, corn planting can begin as early as March 1 in extreme Southern regions and run as late as June 4 in far Northern areas.³

The following tips can help in establishing a good corn stand:

- **Do not plant corn seed too shallow.** Planting less than 1.25 inches deep can result in rootless corn plants or root lodging.⁴ Shallow planting can also increase the risk of injury from some soil-applied herbicides.
- **Do not plant corn seed too deep.** When soil moisture is abundant, plant around 1.5 to 2 inches deep. Planting deeper may delay emergence. If soil is dry, planting at 3 inches into moisture is less risky than planting shallow in anticipation of rain.

Soybean Planting

According to the USDA Field Crop Usual Planting and Harvest Dates Agricultural Handbook, soybean is usually planted from late March in southern Texas in to mid July in the Northeast.³ Soybean seed requires different planting conditions than corn seed. Young soybean seedlings can be more sensitive to environmental conditions after emergence as the growing point is immediately exposed to the elements, whereas the growing point for corn is underground until the V6 growth stage.

Do not plant soybean seed too deep. Soybean seed should be planted at 1 to 1.5 inches deep and no deeper than 2.5 inches.⁵ Planting too deep can use up energy that could be used later by the plant. In addition, planting too deep can inhibit emergence in stressful situations such as soil crusting and compaction.

Waiting for optimum soil conditions and warmer temperatures can help in establishing a healthy corn and soybean crop.

For additional agronomic information, please contact your local seed representative.

Individual results may vary, and performance may vary from location to location and from year to year. This result may not be an indicator of results you may obtain as local growing, soil and weather conditions may vary. Growers should evaluate data from multiple locations and years whenever possible. **ALWAYS READ AND FOLLOW PESTICIDE LABEL DIRECTIONS.** Leaf Design® is a registered trademark of Monsanto Company.
